Wells HCP Hatchery Committees
Statement of Agreement
Regarding the 2023 NNI Hatchery Recalculation Dataset
Approved by the Wells HCP HC
February 16, 2022

Statement

The Wells Habitat Conservation Plan (HCP) Hatchery Committee agrees to the 2023 NNI Hatchery Recalculation data set (Attachment A). The data set includes the release to adult survival rate (SAR) data sources from the identified hatchery programs described in Table 1. These data will be used to recalculate hatchery mitigation values to achieve NNI for the next 10 years (2023 to 2033).

Table 1. SAR data sources used for 2023 Hatchery Recalculation.

Hatchery Program	Brood Years Included	Brood Years (n)	PIT[1] + CWT Harvest SAR Brood Years	CWT[2] SAR Brood Years	Average of CWT and PIT + CWT Harvest SAR Brood Years
Spring Chinook Salmon

Sockeye Salmon[9]					
Wenatchee	2007-2015	9	NA	NA	NA

Notes:

1. PIT + CWT Harvest = SARs to relevant PUD projects, plus CWT based harvest data.
2. CWT = SAR values from PUD Annual Hatchery Monitoring and Evaluation Reports.
3. Nason data were available for 2 brood years: 2013 (PIT+ Downstream CWT harvest) and 2014 (M&E CWT only). Chiwawa data were used for brood years 2007-2012 (see row above).
4. In instances where an initial relevant brood year lacked PIT data, the inclusion of PIT + CWT harvest values began at the first brood year where PIT data became available and alternated thereafter with CWT values.
5. PIT + CWT harvest data were available for only 5 of 9 relevant brood years, therefore PIT + CWT harvest data were used for the available years regardless of sequence.
6. PIT + CWT harvest data were available for only 3 of 9 relevant brood years, therefore PIT + CWT harvest data were used for the available years regardless of sequence.
7. The PIT SAR estimate for Priest Rapids Hatchery BY2006 was unreliable.
8. There is limited CWT data available for steelhead; therefore, PIT-based SARs adjusted for harvest were used. Harvest estimates were calculated by estimating the proportion of upper Columbia hatchery steelhead above McNary Dam and applying that value to the harvest of A-index hatchery (clipped and unclipped) steelhead in treaty and non-treaty, Columbia River fisheries, occurring from the mouth of the Columbia River to Priest Rapids Dam and select dip-in area fisheries between Bonneville and McNary dams. Harvest estimates of hatchery steelhead during conservation fisheries occurring above Priest Rapids Dam within project reservoirs were derived from creel surveys.
9. There is no hatchery program for Wenatchee Sockeye Salmon.

Background

The HCP Hatchery Committees agreed to use the equation described in the Biological Assessment and Management Plan (BAMP) to calculate hatchery compensation for the natural-origin population in the June 16, 2021, SOA "Regarding Methods for 2023 NNI Hatchery Recalculation". The BAMP equation includes counts of natural-origin adult returns and SARs from the hatchery being used for the mitigation. However, the HCP Hatchery Committees were unable to come to a consensus on which data would be used in this equation. The position of the PUDs was that the adult counts and SARs should be derived at the same location, and the dams provided the best location for measuring both. Other members within the committees held positions that adults should be counted at the dams and CWT recoveries should be used for the SAR component of the equation. Ultimately, the HCP Hatchery Committees compromised and agreed to use adult counts at the dams and a combination of CWT recoveries and PIT-tag based SARS. The SARS will alternate between PIT based and CWT based where possible; for summer Chinook with nine relevant brood years, brood year 2013 will be an average of CWT and PIT SARS. This negotiated agreement is not the default for future recalculations.

The HCP Hatchery Committees will endeavor to come to an agreement by December 2022 on a method and data sources for the 2033 recalculation of hatchery compensation for the natural-origin populations, following approval of the 2023 NNI Recalculation Implementation Plan. Additionally, the HCP Hatchery Committees will include the core data needed for the agreed upon future recalculation method in annual reports to ensure these data are available and approved prior to recalculation.

2024-2033 RECALCULATION DATA SUMMARY

Chelan PUD, Douglas PUD, Grant PUD

FEBRUARY 2022

Introduction

This document summarizes data used to recalculate hatchery compensation for Douglas, Chelan, and Grant PUDs for future release years 2024-2033. The period of record for this effort includes natural origin adult return years 2011-2020.

Relevant Brood Years

The brood years contributing to this period vary by species and are summarized in Tables 1-4.

Table 1. Chinook Salmon brood years contributing to adult return years 2011-2020.

Notes: Grey background delineates return years 2011-2020. BY = brood year, RY = release year, O = ocean year. 2008 is the first relevant brood year for Coho.

Natural-Origin Adult Returns

The adult return years evaluated for the current recalculation effort cover the period of 2011 to 2020. The average numbers of natural-origin adult returns at each project during this period are summarized in Table 5. Species that are compensated through alternative PUD funding agreements (e.g., Coho, Okanogan Sockeye, Summer Chinook above Wells) are not addressed in this document.

Table 5. Estimated average natural-origin adult passage at Wells, Rocky Reach, Rock Island, Priest Rapids hydroelectric projects during the period of 2011-2020.

Project	Species	Note	Average Count
Wells	Spring Chinook		656
Wells	Steelhead		1,353
Wells	Summer and Fall Chinook		24,849
Wells	Coho		42
Rocky Reach	Spring Chinook		901
Rocky Reach	Steelhead		1,728
Rocky Reach	Summer and Fall Chinook		33,434
Rocky Reach	Coho		58
Rock Island	Sockeye	Wenatchee Only	38,173
Rock Island	Spring Chinook	Nadir Method	1,667
Rock Island	Steelhead		2,632
Rock Island	Summer and Fall Chinook		43,064
Rock Island	Coho		335
Priest Rapids	Fall Chinook		11,679
Priest Rapids	Summer Chinook		32,882
Priest Rapids	Spring Chinook	Nadir Method	1,781
Priest Rapids	Steelhead		3,123

The detailed methods used to calculate adult returns for each species are summarized in Figures 1-17 below and described in Table 6. Annual calculated estimates are bounded by a green outline and the average number of fish from 2011-2020 is highlighted in orange within each figure.

Comparison Between Natural-origin Adult Enumeration Methods for 2013 and 2023 Recalculation Efforts

Table 6. Summary and comparison of methods used during 2013 and 2023 recalculation efforts

Project	Species	2013 Method Summary	2023 Method Summary
Wells	Spring Chinook	Natural-origin spring Chinook returns at Wells were calculated using stock assessment data provided by WDFW. Returns were adjusted for broodstock removals, fallback, and double counts.	Same
Wells	Steelhead	Natural-origin steelhead returns at Wells were calculated using Wells stock assessment data provided by WDFW. Returns were adjusted for broodstock removals, fallback, and double counts.	Same
Wells	Summer and Fall Chinook	Funding for CJH. Recalculation was not used	Summer Chinook adults were enumerated at Wells using total Chinook counts from DART and then subtracting spring-Chinook based on stock assessments at Wells by WDFW. The proportion of natural-origin summer Chinook were also obtained from stock assessments at Wells and then applied to the remainder to estimate total natural-origin summer Chinook passage.
Wells	Coho	N/A	Hatchery- and natural-origin proportions were applied to annual DART counts at Wells. Hatchery- and natural-origin proportions were provided by the Yakama Nation through M&E reporting on Methow program (Caisman et al. 2020).
Rocky Reach	Spring Chinook	Natural-origin spring Chinook returns at Rocky Reach were calculated by first apportioning spring Chinook by average nadir date and then subtracting unmarked hatchery fish based on 1) Wells/WDFW stock assessment data and 2) PIT expansion of HORs using conversion rate from RR to Wells. The availability of PIT data was limited to HORs and only a	Natural-origin spring Chinook returns at Rocky Reach were calculated based on the conversion rate of NORs from RR to Wells and Entiat escapement. Specifically, the availability of 1) PIT data for natural origin fish and all return years (2011-2020) allowed for the direct calculation of natural origin spring Chinook at Rocky Reach using 1) Wells/WDFW stock assessment data for NORs and 2) PIT expansion of NORs using conversion rate from Wells. NORs returning

Project	Species	2013 Method Summary	2023 Method Summary
		fraction of return years, therefore it was only possible to remove unmarked hatchery fish for 2006-2010 return years.	to the Entiat (USFWS data) were subsequently added to the expanded RR count. This method directly solves for NORs and reflects data that were not previously available during the earlier recalculation. In addition, this approach uses 10 return years (instead of 5 return years) because of the availability of NOR PIT data for all return years.
Rocky Reach	Steelhead	Natural-origin steelhead returns at Rocky Reach were calculated by adjusting RR window counts by NOR percentage using data obtained from Wells stock assessment efforts.	Natural-origin steelhead returns at Rocky Reach were calculated by adjusting window counts by 1) NOR percentage using Wells stock assessment data, and 2) fallback correction factor[1] data for 2012-2020 return years were used to correct window counts for multiple ascension attempts. Entiat steelhead were considered separately because they do not convert to Wells dam and therefore may influence the hatchery to natural-origin ratio. The estimated number of Entiat NORs were subsequently added to the total for Rocky Reach. The previous recalculation method did not account for the Entiat River specifically and therefore may have had additional error associated with the hatchery to natural-origin ratio
Rocky Reach	Summer and Fall Chinook	Natural-origin summer/fall Chinook counts were based on window counts with stock apportionment by nadir date as adjusted by the percentage of NORs. Nadir apportionment was based on the average nadir date of all return years. Hatchery and natural-origin percentages were determined using adipose fin observations from fish counting windows and the percent NOR was applied to the nadir count. Clipped and unclipped adult data records were only available in 2002 and thereafter.	Natural-origin summer/fall Chinook counts were based on window counts with stock apportionment by nadir date as adjusted by 1) the percentage of NORs, and 2) fallback correction factor[1] data. Nadir apportionment was based on 1) individual return years and 2) summer and fall runs within each year. Hatchery and natural-origin percentages were determined using adipose fin observations from fish counting windows for all return years. The estimates for the current recalculation effort are likely to be more accurate than the previous recalculation effort because the individual nadir year approach was used instead of the "average" to capture annual variability in run timing. In addition, fallback correction factor[1] data were available and used to correct window counts for multiple ascension attempts for both summer and fall Chinook.
Rocky Reach	Coho	N/A	Hatchery- and natural-origin proportions were applied to annual DART counts at Rocky Reach. Hatchery- and natural-origin proportions were provided by the Yakama Nation through M&E reporting on Methow program (Caisman et al. 2020).
Rock Island	Sockeye	Wenatchee natural-origin sockeye returns at Rock Island were calculated by 1) subtracting window counts at Rock	Wenatchee natural-origin sockeye returns at Rock Island were calculated by 1) subtracting window counts at Rock Island from

Project	Species	2013 Method Summary	2023 Method Summary
		Island from window counts at Rocky Reach and 2) applying NOR percentage data obtained from PRD stock assessment efforts.	window counts at Rocky Reach and 2) applying fallback correction factor[1] data to correct window counts for multiple ascension attempts. There was no hatchery program in the Wenatchee during the period of record so NOR percentage was not considered.
Rock Island	Spring Chinook	Natural-origin spring Chinook returns at Rock Island were calculated by first apportioning spring Chinook by average nadir date and then subtracting unmarked hatchery fish based on 1) Wells/WDFW stock assessment data and 2) PIT expansion of HORs using conversion rate from RI to Wells. The availability of PIT data was limited to HORs and only a fraction of return years, therefore it was only possible to remove unmarked hatchery fish for 2006-2010 return years.	The nadir method first apportioned spring Chinook from window counts using the nadir date for each return year. For the Wenatchee River, spring Chinook counts were subsequently adjusted by 1) the percentage of NORs observed in the Wenatchee River, and 2) fallback correction factor[1] data. NORs upstream of Rock Island were estimated using a PIT tag-based expansion derived from the RI to RR conversion rate of NORs. This method is an improvement over the previous recalculation approach because it solves for NORs directly. In addition, the nadir method used uses new data sources that were not previously available during the earlier recalculation (e.g., NOR PIT data) and expand the period of record from 5 years (2006-2010) to 10 years (2011-2020).
Rock Island	Steelhead	Natural-origin steelhead returns at Rock Island were calculated by adjusting RI window counts by NOR percentage obtained from PRD stock assessment. The PRD stock assessment historically relied on visual assessments of elastomer tags to identify unclipped hatchery fish (up to brood year 2010 and return year 2014). However, elastomer tag loss was not corrected for and therefore PRD estimates likely inflated the number of NORs present. In addition, PRD stock assessment results include significant numbers of hatchery origin returns from Ringold and other unidentified hatchery locations. As a result, hatchery-origin to natural-origin ratios derived from PRD stock assessment data are not expected to be reflective of ratios expected for upstream tributaries.	Natural-origin steelhead returns at Rock Island were calculated by 1) estimating Wenatchee origin NORs and adding these to 2) PIT expanded NORs calculated for RR. The Wenatchee NOR component was calculated by subtracting RR window counts from RI window counts (after applying fallback correction factor[1] data to correct window counts for multiple ascension attempts) and then applying the percentage NOR obtained from Dryden stock assessment activities. The PIT expanded NOR calculation for RR was based on the conversion rate for NORs from RI to RR. This method uses natural origin return PIT data that were not previously available and uses stock assessment data from WDFW collected at two sources (Dryden and Wells). The use of Dryden and Wells stock assessment data allows for comparison with other M&E tributary data to verify count accuracy. For example, the estimated average Dryden-based count of Wenatchee steelhead is 887 for return years 2011-2020 which is higher but similar to the average Wenatchee NORs for contributing brood years (Avg = 865; BY =

Project	Species	2013 Method Summary	2023 Method Summary
			2008-2014) and more than the average of the combined harvest, escapement, and brood collection of NORs for return years 2011-2020 (Avg = 547). In short, the calculated adult returns numbers are likely higher than the actual number of NORs present.
Rock Island	Summer and Fall Chinook	Natural-origin summer/fall Chinook counts were based on window counts with stock apportionment by nadir date as adjusted by the percentage of NORs. Nadir apportionment was based on the average nadir date of all return years. Hatchery and natural-origin percentages were determined using adipose fin observations from fish counting windows and the percent NOR was applied to the nadir count. Clipped and unclipped adult data records were only available in 2002 and thereafter. Fall Chinook overshoots from PRD were corrected for by using PIT detections at RI and juvenile fall Chinook marking data from PRD	Natural-origin summer/fall Chinook counts were based on window counts with stock apportionment by nadir date as adjusted by 1) the percentage of NORs, and 2) fallback correction factor[1] data. Nadir apportionment was based on 1) individual return years and 2) summer and fall runs within each year. Adipose-present hatchery-origin fall Chinook from PR hatchery were corrected for by using PIT detections at RI and juvenile fall Chinook marking data from PR hatchery. Hatchery and natural-origin percentages were determined using adipose fin observations from fish counting windows for all return years. The estimates for the current recalculation effort are likely to be more accurate than the previous recalculation effort because the individual nadir year approach was used instead of the "average" to capture annual variability in run timing. In addition, fallback correction factor[1] data were available and used to correct window counts for multiple ascension attempts for both summer and fall Chinook.
Rock Island	Coho	N/A	Hatchery- and natural-origin proportions were applied to annual DART counts at Rock Island. Hatchery- and natural-origin proportions were provided by the Yakama Nation through M&E reporting on Methow and Wenatchee programs (Caisman et al. 2020).
Priest Rapids	Fall Chinook	Natural-origin fall Chinook counts were based on window counts at Rock Island and stock apportionment by nadir date as adjusted by the percentage of NORs. Nadir apportionment was based on the average nadir date of all return years. Hatchery and natural-origin percentages were determined using adipose fin observations from fish counting windows and the percent NOR was applied to the nadir count. Clipped and unclipped adult data records were only available between 2007 and 2010, and therefore limited the period of record to 4 years.	Natural-origin fall Chinook counts were based on window counts at Rock Island with stock apportionment by nadir date as adjusted by 1) the percentage of NORs, and 2) reascension correction factor[2] data. Nadir apportionment was based on 1) individual return years and 2) summer and fall runs within each year. Adipose-present hatchery-origin fall Chinook from PR hatchery were corrected for by using PIT detections at RI and juvenile fall Chinook marking data from PR hatchery. Hatchery and natural-origin percentages were determined using adipose fin observations from fish counting windows for all return years. The estimates for the current recalculation effort are likely to be more accurate than the previous recalculation effort

Project	Species	2013 Method Summary	2023 Method Summary
			because the individual nadir year approach was used instead of the "average" to capture annual variability in run timing. In addition, reascension correction factor[2] data were available and used to correct window counts for multiple ascension attempts for both summer and fall Chinook.
Priest Rapids	Spring Chinook	Natural-origin spring Chinook counts were based on window counts at Priest Rapids and stock apportionment by nadir date as adjusted by the percentage of NORs. Nadir apportionment was based on the average nadir date of all return years. Natural-origin spring Chinook salmon were estimated as unclipped fish at Priest Rapids Dam minus unclipped hatchery fish at Wells adjusted by conversion rates between Priest Rapids Dam and Wells Dam. Clipped and unclipped adult data records were only available between 2007 and 2010, and therefore limited the period of record to 4 years.	Natural-origin spring Chinook counts at Priest Rapids use similar method as Rock Island spring Chinook except the counting location and PIT tag expansion uses Priest Rapids as the control point (not Rock Island). See Rock Island 2023 spring Chinook method. The new method is an improvement over the previous recalculation approach because NORs are calculated directly and new data sources expand the period of record from 4 years (2007-2010) to 10 years (2011-2020).
Priest Rapids	Steelhead	Natural origin steelhead counts were based on window counts at Priest Rapids Dam as adjusted by NOR percentage. NOR percentage was calculated using stock assessment data collected from PRD.	Natural-origin steelhead counts at Priest Rapids use similar method as Rock Island steelhead except the counting location and PIT tag expansion uses Priest Rapids as control point (not Rock Island). See Rock Island 2023 steelhead method.
Priest Rapids	Summer Chinook	Natural-origin Summer Chinook counts were based on window counts at Priest Rapids and stock apportionment by nadir date as adjusted by the percentage of NORs. Nadir apportionment was based on the average nadir date of all return years. Hatchery and natural-origin percentages were determined using adipose fin observations from fish counting windows and the percent NOR was applied to the nadir count. Clipped and unclipped adult data records were only available between 2007 and 2010, and therefore limited the period of record to 4 years.	Natural-origin Summer Chinook counts were based on window counts at Priest Rapids and stock apportionment by nadir date as adjusted by 1) the percentage of NORs and 2) reascension correction[2] factor. Nadir apportionment was based on the individual nadir date for each return year. Hatchery and natural-origin percentages were determined using adipose fin observations from fish counting windows and the percent NOR was applied to the nadir count. Clipped and unclipped adult data records were available for all return years. The estimates for the current recalculation effort are likely to be more accurate than the previous recalculation effort because the individual nadir year approach was used instead of the "average" to capture annual variability in run timing. In addition, window counts were corrected for multiple ascension attempts and counts for all return years have been included.

Notes

1. The fallback correction factor is used to adjust window counts for multiple ascension attempts or fallback to attain estimates of run size. The fallback correction factor is estimated based on observed PIT-tag detections in the adult ladders and reflect the ratio of number of unique fish to number of passage attempts. Fallback correction factors were calculated by Columbia Basin Research: *Buchanan, R.A., and J. R. Skalski. 2012-2020. Detection Efficiencies at Rock Island, Rocky Reach, and Tumwater Dam Adult Ladders (2012-2020). Columbia Basin Research, School of Aquatic and Fishery Sciences, University of Washington*

2. Fallback Correction Factor = Reascension Correction Factor

Project Survival and Unavoidable Project Mortality Data

Project survival and associated unavoidable project mortality values are summarized in Table 7. Updated values for Rock Island yearling Chinook are anticipated upon completion of a project survival study in 2021.

Table 7. Summary of project survival and unavoidable project mortality data based on completed survival studies or other agreements.

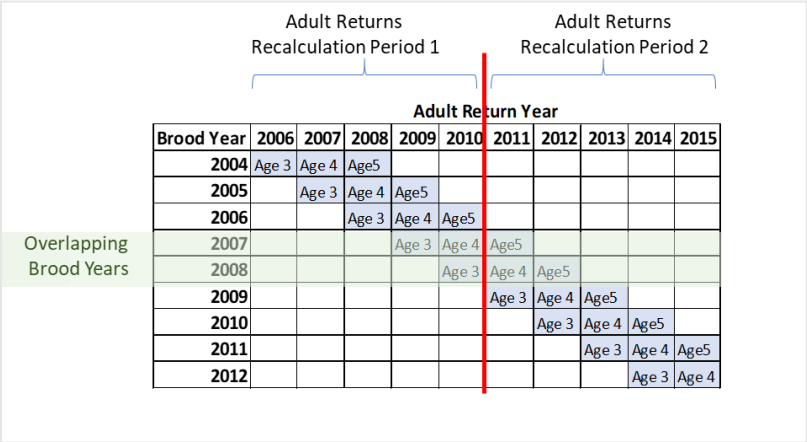
SAR Data

Smolt to adult return (SAR) rates were calculated for individual public utility district hatchery programs. The brood years included in the calculations represent those brood years that are expected to contribute to the adult return years of 2011-2020 (see Tables 1-4). This approach uses a 10-year adult return window and maximizes the number of relevant brood year SARs that are included. It should be noted that if the brood year SARs are not linked with their associated adult return years, changes in hatchery performance will be muted by variability in ocean productivity and the resultant hatchery compensation values will primarily reflect the extent of the mismatch between the ocean productivity experienced by adult returns and the decoupled brood years (as opposed to hatchery performance). For the current recalculation effort, complete brood year SARs from the previous recalculation were not used. However, because a single brood year may span multiple adult return years, it is impossible to generate continuous brood year SARs that do not overlap recalculation periods (Figure 19). Therefore, an incomplete brood year from one recalculation period may contribute to and remain relevant in the next recalculation period as it is updated with additional returns.



Brood Year	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
2004	Age 3	Age 4	Age5							
2005		Age 3	Age 4	Age5						
2006			Age 3	Age 4	Age5					
2007				Age 3	Age 4	Age5				
2008					Age 3	Age 4	Age5			
2009						Age 3	Age 4	Age5		
2010							Age 3	Age 4	Age5	
2011								Age 3	Age 4	Age5
2012									Age 3	Age 4

Figure 18. Illustration of brood years overlapping recalculation periods

The following sections provide an overview of the SAR calculation method for individual species and stocks. For Chinook stocks, the proposed method for calculating SARs includes: Alternating between 1) PIT data from Project or upstream detection locations plus CWT data from downstream harvest ["PIT + CWT harvest"]; and 2) CWT-based SARs obtained directly from annual reports ["CWT"; e.g., Hillman et al. 2021].

The alternation sequence begins with the first brood year populated with a PIT + CWT harvest value followed by the second brood year populated with a CWT value and continues thereafter for all relevant brood years (e.g., BY1 = PIT + CWT harvest; BY2 = CWT; BY3 = PIT + CWT harvest; BY 4 = CWT; etc.). For spring and fall Chinook with 8 relevant brood years, SAR data includes 4 brood years populated with PIT + CWT harvest data and 4 brood years populated with CWT data. For summer Chinook with 9 relevant brood years, SAR data includes 4 brood years populated with PIT + CWT harvest data and 4 brood years populated with CWT data and 1 brood year with the average of CWT and PIT + CWT harvest data (i.e., Carlton, Dryden and Chelan Falls Summer Chinook). In instances where an initial relevant brood year

lacked PIT data, the inclusion of PIT + CWT harvest values began at the first brood year where PIT data became available and alternated thereafter with CWT values. Where PIT data were available for less than the target number of brood years (i.e., 4 years for spring and fall Chinook and 5 years for summer Chinook), all available PIT + CWT harvest data were used regardless of sequence with CWT data. For Summer Chinook, exceptions to the previously described method include Wells (100% CWT) and Similkameen (SAR data includes 3 brood years populated with PIT + CWT harvest data and 6 brood years populated with CWT data).

After selecting the SAR data for the relevant brood years (e.g., PIT + CWT harvest or CWT or a combination thereof), the arithmetic mean of all values was calculated for each stock.

The mixing of two different SAR data sets for Chinook Salmon has been proposed as a compromise to facilitate continued progress with the current hatchery recalculation process as there is disagreement among the Hatchery Committee members on how SARs should be calculated to support hatchery recalculation.

Spring Chinook

For Spring Chinook, PIT + CWT harvest data were obtained from the following sources: 1) PIT tag data from release to detection at individual hydroprojects or upstream location, and 2) CWT harvest data for downstream ocean, Zone 1-5 commercial, recreational, and Tribal fisheries. CWT data were obtained from annual reports (e.g., Hillman et al. 2021; Snow et al. 2021). PIT data for RI based on conversion from PRD

Summer Chinook

For Summer Chinook, PIT + CWT harvest data were obtained from the following sources: 1) PIT tag data from release to adult detection at individual hydroprojects or upstream locations, and 2) CWT harvest data for downstream ocean, Zone 1-5 commercial, and Zone 6 Tribal fisheries. CWT data were obtained from annual reports (e.g., Hillman et al. 2021; Snow et al. 2021)

Fall Chinook

For Fall Chinook PIT + CWT harvest were obtained from the following sources: 1) PIT tag data from release to adult detection at McNary Dam, and 2) CWT data obtained from downstream ocean, Zone 1-5 commercial, recreational, and Tribal fisheries. McNary Dam was used as a control point because significant numbers of adult fall Chinook spawners use the Hanford Reach. CWT data were obtained from annual reports (e.g., Richards and Pearsons 2021)

Steelhead

Summer Steelhead SARs were calculated using 1) PIT tag data from release to detection at Priest Rapids or 2) stock assessment data if PIT tags were not available for a given brood year. PIT SAR estimates for release to Priest Rapids were corrected for downstream harvest using harvest rate of 0.168 provided by WDFW. SAR estimates for RI were also corrected by applying a conversion rate factor from Priest Rapids to Rock Island. SAR estimates for Wells were also corrected by applying a conversion rate factor from Priest Rapids to Wells and by applying harvest rate factor from WDFW for fisheries between Rock Island and Wells (2011-2015). For all project SAR estimates, harvest rates were calculated by estimating the proportion of upper Columbia hatchery steelhead above McNary Dam and applying that value to the harvest of A-index hatchery (clipped and unclipped) steelhead in treaty and non-treaty, Columbia River

fisheries, occurring from the mouth of the Columbia River to Priest Rapids Dam and select dip-in area fisheries between Bonneville and McNary dams. Harvest estimates of hatchery steelhead during conservation fisheries occurring above Priest Rapids Dam within project reservoirs were derived from creel surveys

Sockeye

Hatchery production did not occur in the Wenatchee basin and hatchery SARs were not calculated. Therefore, natural-origin SARs were calculated based on run reconstruction using smolt production and adult return estimates from Hillman et al. 2021.

Table 8 summarizes the calculated SARs for the PUD hatchery facilities and includes the brood years that were considered (based on Tables 1-3). Table 9 provides specific detail for individual brood year SARs.

Coho

Coho SARs were obtained from the Yakama Nation Mid-Columbia Coho Reintroduction Monitoring and Evaluation Report for 2019 for the Wenatchee and Methow programs. PIT data were also obtained from the WINT and WINTBC programs to support SAR estimates to Wells for the Twisp program.

Table 8. Summary of average hatchery smolt to adult return data for public utility district hatchery programs

Species	Program	Brood Years Included (Current Recalculation)	Brood Years included (Previous Recalculation)	Avg. SAR[1]	Project-based SAR: Avg. Priest Rapids SAR	Project-based SAR: Avg. Rock Island SAR	Project-based SAR: Avg. Wells SAR	Data Used
Spring Chinook								
	Chiwawa	2007-2014; N = 8	2002-2004, 2007[2], 2008[2]		0.578%	0.575%		Project/Upstream PIT + Downstream CWT harvest: 2007, 2009, 2011, 2013; M&E CWT only: 2008, 2010, 2012, 2014. RI PIT values based on conversion from PRD
